Introduction

The human brain is an amazing organ. It mediates all of our thoughts, feelings and behaviors. It allows us to create, share and hope. It allows us to communicate and connect, to teach and to learn. The brain allows us our humanity.

In order to do all of these wonderful things, our brain must organize its 100 billion individual nerve cells (neurons) into efficient systems to sense, process, perceive, store and act on the continuous bath of sensations sights, sounds, tastes, smells and touch - in the environment. Furthermore, our brains do not just automatically pop into existence, capable of all these wonderful functions. The brain begins to develop in utero from just a few cells. And in within a few short years has grown to be 85% adult-size. The brain *grows* to become a dynamic ever-changing biological systems which gives us the capacity to love, create, communicate or think. Our brain becomes a product of our genetic potential and our history of experience.

Experiences - repetitive, consistent, predictable and nurturing experiences - are required to express the underlying genetic potential of each child. And it is becoming increasingly clear that it is the experiences of early childhood that play a key role in determining the foundational organization and capabilities of the brain (Schore, 1997; Perry, 1994).

The experiences, environments and opportunities we provide our children help determine their strengths and vulnerabilities. If the child's world is chaotic, violent and emotionally or cognitively impoverished, their potential will remain unexpressed. If the child's world is safe, nurturing and rich in social, emotional and cognitive opportunities, he or she will flourish. And central to a child's healthy development is the opportunity to act on their natural curiosity – to explore, to play and, thereby, to learn.

Play, more than any other activity, fuels healthy development of children – and, the continued healthy development of adults. This is a bold statement. To judge this statement, we must consider what play is and how the human brain develops and changes.

What is Play and Why is it Important?

Play takes many forms but the heart of all play is pleasure. If it isn't fun, it isn't play. We play from birth on – we play using our bodies (e.g., building with blocks) and our minds (e.g., fantasy play). We use words to play (e.g., jokes, wit, humor) and we use props (e.g., blocks, toys, games). While the exact nature of play evolves, becoming more complex as we grow, play at all ages brings pleasure. And with pleasure comes the powerful drive to repeat the pleasurable activity. And with repetition, comes mastery. Mastery brings a sense of accomplishment and confidence. The more comfortable a child feels with the world, the more likely she will explore, discover, master and learn. This cycle starts with curiosity.

Curiosity, a neurobiological feature of many primates, drives exploratory play. Play can satisfy curiosity as the child explores their environment, thereby, expanding their catalogue of experience. When the child explores, she discovers. A wonderful cycle of learning is driven by the pleasure in play. A child is curious; she explores and discovers. The discovery brings pleasure; the pleasure leads to repetition and practice. Practice brings mastery; mastery brings the pleasure and confidence to once again act on curiosity. All learning – emotional, social, motor and cognitive – is accelerated and facilitated by repetition fueled by the pleasure of play.

Simple principles of neurodevelopment match the observations related to play that have been made by academics, clinicians and parents over the years. Neurodevelopment, while very complex, has a number of core concepts and principles that can illustrate the central, crucial role of play in healthy development.

Neurodevelopment Principle One: Sequential Development. The brain, at birth, is undeveloped. During its development it organizes and grows in a sequential fashion, starting from the lowest, most regulatory regions of the brain and proceeding up through the more complex parts of the brain responsible for more complex functions. Healthy development of one region/capability is dependent upon the healthy development of lower brain regions that take place earlier in the process (see Figure 1).

Play during development, therefore, parallels this sequential neurodevelopmental process. In early childhood, when the brain is developing motor-vestibular capabilities, for example, there is much more large motor play than in adolescence. Play opportunities for the child must be provided in an appropriate sequence and matched to the child's level of neurodevelopment. In turn, this matching process is dependent upon adequate assessment of the child's development in the key areas of physical/motor, behavioral, emotional, social and cognitive domains.

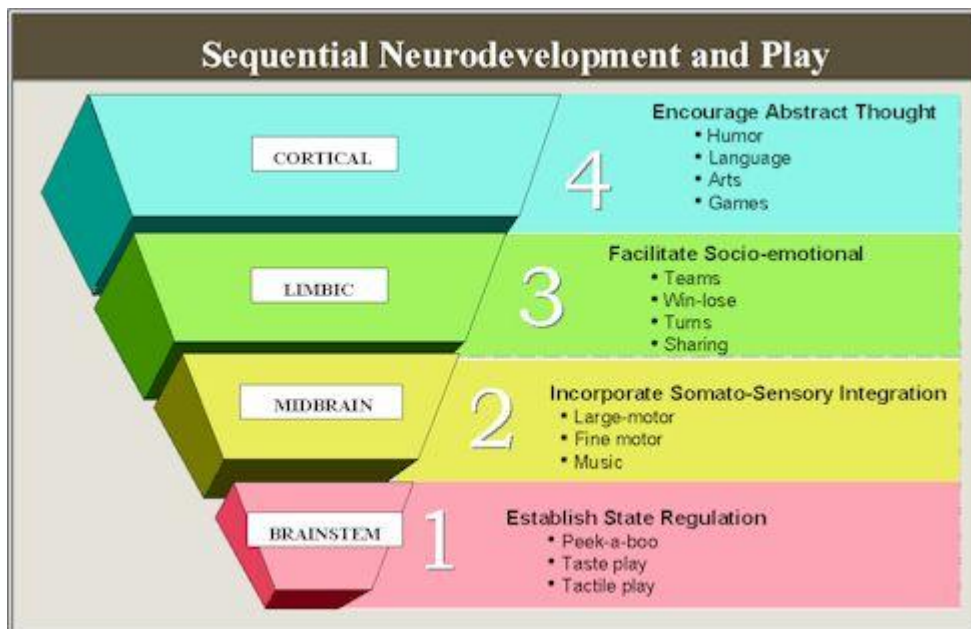

Figure 1: *The Hierarchical Structure of the Human Brain:* The human brain is organized and develops in a hierarchical fashion. The lowest and most simple areas develop first, followed in sequence by more complex areas that mediate more complex functions. Play activities of children mirror this process and facilitate healthy development of the brain. Babies play at the nipple, toddlers practice motor skills, and fantasy play encourages socio-emotional and cognitive development. As children grow, the complexity of play grows. Solitary, parallel, dyadic and then group play develops in sequence with the developing social capabilities of the child. At each stage of development, it is play and the repetitive elements of play that help organize neural systems which will ultimately mediate more complex motor, social, emotional and cognitive skills.

Neurodevelopment Principle Two: Use-dependent Development. The normal organization of any brain area or capability is 'use'-dependent. Neurodevelopment is dependent upon the presence, pattern, frequency and timing experiences during development. The more patterned activity (e.g., music, reading, conversation), the more the brain regions responsible for these tasks will organize and be functionally 'healthy'. The implications of this are profound. Patterned repetitive activity results in patterned neural activity that changes the brain. These experiences help build in the neural capacity to better perform those functions (i.e., hearing language helps develop speech and language capabilities; practicing piano develops fine motor and rhythm-reading capabilities and reading increases capacity for verbal comprehension and abstract reasoning). Children exposed to consistent, predictable, nurturing and enriched experiences will develop neurobiological capabilities that will increase the child's chance for health, happiness, productivity and creativity. Conversely this means that the child with neglect, chaotic, and terrorizing environments will have significant problems in all domains of functioning (see Perry 1995; 1997).

Play has a crucial role in providing the repetitive experiences that can improve and express the potentials in all areas of the human brain. Depending upon the nature of the play, growth and change in all parts of the brain can be facilitated. The more opportunities for enriched and complex play, the more repetition will take place. As we think about the importance of play we can never underestimate the need for consistent, predictable, patterned and frequent opportunities for play in a child's life. This means that the major providers of the experiences in the child's life - caregivers, teachers, and parents - must appreciate the role of play and pleasure in overall learning.

Conceptual Principle Three: Windows of Opportunity. Much of this sequential and use dependent development of the brain takes place in early childhood. This means that of all the experiences throughout the life of an individual, the organizing experiences of early childhood have the most powerful and enduring effects on brain organization and functioning! Society does not capitalize on this window of opportunity in early childhood. Indeed, we typically wait until a child is so impaired and dysfunctional, acting out and failing in school, before we initiate services. Those few resources that are dedicated to early childhood tend to be inefficient and unfocused.

With play, we have an inexpensive and efficient means to help children develop. Proactive is better than reactive. Simple music and movement activities provided early in life for high-risk children, for example, appears to have powerful and positive impact on young children. We must teach young mothers and caregivers how important it is to play with their young children. The best toy for a young child is the invested, caring adult - someone to pay attention, to engage and to play with the child using words, song, touch and smile.

Play and Exploration

Play and exploration are crucial activities for young children. They help the child's brain develop in optimal ways. Child sensitive spaces, semi-structured activities and opportunities for exploration are safe, nurturing and enriched in developmentally appropriate stimulation should be the core elements of all child-focused programs. Play and exploration grow the brain - healthy play and exploration grows healthy brains.

How does play help your child grow?

Through play, a child's sense of who she is can become more defined and integrated. As she learns about herself and the world, she acquires a wide range of important developmental, social, and cognitive skills, as well as positive inner traits, that help form the basis for happiness, productivity and a healthy future. Play-related skill building tracks with neurodevelopment. As described above, the brain organizes from the bottom to the top

Gross motor skills, such as walking, kicking, or skipping, can be enhanced when a toddler pushes a toy grocery cart or an older child jumps rope. When a young child kicks a ball across the room, she is practicing coordination by balancing on one foot to kick with the other. She is additionally developing larger muscle control, tone and flexibility, qualities that may help her score the winning goal when she is old enough to play soccer.

Children can develop advanced fine motor and manipulation skills while playing as they use their fingers to build and color a sign for a backyard tree house. When throwing and catching a ball, they are practicing hand-eye

coordination and their ability to grasp. They are even developing the muscle control and coordination needed to one day write a letter to a friend, as they scribble with a pencil on paper.

Children have opportunities to enhance their language skills through play by talking and singing with other children. A child's interactions with and repetition of his playmates help him master the semantics of language as he participates in spontaneous rhyming and word play. While having fun, he increases his play-related speech, his sentence length, and his vocabulary.

The child's cognitive, or mental, abilities can also be enhanced by play. A child's play often involves physical and mental trial and error, problem-solving tasks, and an ability to discriminate between relevant and irrelevant information. Play requires the child to make choices and direct activities and often involves strategizing, or planning, to reach a goal. Through pleasurable play, children often become motivated and perseverant, qualities that frequently may later translate into the classroom.

While enjoying their play, children can acquire a wide range of interpersonal/social skills, ranging from communication to cooperation. When children argue about who stepped "out of bounds" and agree upon a "do over," they are learning how to negotiate, compromise and work together. They are learning about teamwork when they huddle together and decide how they will position themselves for the next shot. The child gains an understanding about those around him and may become more empathetic and less egocentric. When playing with peers, children are developing a learning system of social rules, including ways to control themselves and tolerate their frustrations in a social setting.

Creating a healthy environment to optimize play and learning

A child will play when she feels safe. And to a child, feeling safe has little to do with outlet plugs and childproof cabinets. A child's sense of safety stems from a calm and **predictable** world – one in which she knows what will

happen next. This means her life is fairly consistent from one day to the next – and the adults in her world are predictable, consistent and, ideally, attentive, attuned and attached. She knows her caregiver is there for her to feed her, protect her and comfort her. You can make a child's world more predictable by keeping her on a daily schedule. For example, she wakes, eats meals and bathes roughly at the same time every day. Significant changes to her daily routine (for example, frequent home moves) are kept to a minimum. Predictability will help eliminate the element of surprise. In an unpredictable world with no routine, children may be anxious. Anxiety kills curiosity. A child that feels safe and is in familiar space will be curious and will seek novelty. A child that is anxious or in an unfamiliar setting will be unwilling to try new things.

A child's environment should also be rich in sights, sounds, smells, tastes and touch. Environments rich in sensory experiences stimulate the child's brain and give him/her new information about the world. For a child, a sensory-rich experience could be as simple as the smell of blueberry muffins baking in the kitchen or the touch of a velvet pillow to the face. It is important for caregivers to recognize the importance of sensory experiences to a child. Caregivers should also recognize that too much stimulation could overwhelm a child. For example, one toy with bells and whistles might be interesting to a child, but many noise-making toys might over stimulate him/her. Caregivers should note that television is not considered a sensory-enriched experience for a child.

In today's world we often underestimate the importance of play. We over schedule our children with educational or structured activities that often inhibit spontaneous, curiosity-driven exploration. In the end, if we want to help our children meet their potential, we must allow children to have free time, spontaneous play and safe and enriched play and learning environments.

About the Authors

Bruce D. Perry, M.D., Ph.D. is the Senior Fellow for The ChildTrauma Academy, a not-for-profit organization working to improve the lives of maltreated children. From 1992 to 2001, Dr. Perry served as the Thomas S. Trammell Research Professor of Child Psychiatry at Baylor College of Medicine and Chief of Psychiatry at Texas Children's Hospital in Houston, Texas. He has also served as the Medical Director for Provincial Programs in Children's Mental Health for the Alberta Mental Health Board.

Lea Hogan, M.Ed. served as a clinician at the ChildTrauma Academy where she was the project director of the Early Childhood and Neurodevelopment Curriculum Project. Ms. Hogan has extensive clinical experience working with maltreated children and has been active in the ChildTrauma Music and Movement projects.

Sarah J. Marlin graduated magna cum laude from Columbia University, New York, NY with a Bachelor of Arts in Biology. At the time of this piece, Ms. Marlin was a medical student at Baylor College of Medicine, Houston, TX.

By Bruce Duncan Perry, M.D., Ph.D.

"Whas'at? Whas'at?"

—A question from a 3-year-old boy asked of his mother over and over as they walked through the zoo.

Children are such curious creatures. They explore, question, and wonder, and by doing so, learn. From the moment of birth, likely even before, humans are drawn to new things. When we are curious about something new, we want to explore it. And while exploring we discover. By turning the light switch on and off over and over again, the toddler is learning about cause and effect. By pouring water into a dozen different-shaped containers and on the floor and over clothes, the 4-year-old is learning pre-concepts of mass and volume. A child discovers the sweetness of chocolate, the bitterness of lemon, the heat of the radiator, and the cold of ice.

The Cycle of Learning

If a child stays curious, he will continue to explore and discover. The 5-year-old finds tadpoles in a tiny pool of mud on the playground. This discovery gives him pleasure. When he experiences the joy of discovery, he will want to repeat his exploration of the pond. [Pleasure leads to repetition.] Each day, he and his classmates return. The tadpoles grow legs. [Repetition leads to mastery.] The children learn that tadpoles become frogs — a concrete example of a complex biological process. Mastery — in this case, understanding that tadpoles become frogs — leads to confidence. Confidence increases a willingness to act on curiosity — to explore, discover, and learn. "Can we bring tadpoles into the class? How do other baby animals grow up? Why don't dog babies lose their tails?" This positive cycle of learning is fueled by curiosity and the pleasure that comes from discovery and mastery.

Shared Discovery

What is most pleasurable about discovery and mastery is sharing it with someone else. ("Teacher, come look! Tadpoles!") We are social creatures. The most positive reinforcement — the greatest reward and the greatest pleasure — comes from the adoring and admiring gaze, comments and support from someone we love and respect. The teacher smiles, claps, and comments, "You are great. Look at all these tadpoles! You are our science expert!" This rewarding approval causes a surge of pleasure and pride that can sustain the child through new challenges and frustrations. Approval can generalize and help build confidence and self-esteem. So later in the day, when this boy is struggling with the introduction of simple math concepts, rather than eroding his esteem by thinking, "I'm stupid, I don't understand," he can think, "I don't get this, but I'm the one who knows about tadpoles."

Constrained Curiosity

For too many children, curiosity fades. Curiosity dimmed is a future denied. Our potential — emotional, social, and cognitive — is expressed through the quantity and quality of our experiences. And the less-curious child will make fewer new friends, join fewer social groups, read fewer books, and take fewer hikes. The less-curious child is harder to teach because he is harder to inspire, enthuse, and motivate.

There are three common ways adults constrain or even crush the enthusiastic exploration of the curious child: 1) fear, 2) disapproval and 3) absence.

Fear: Fear kills curiosity. When the child's world is chaotic or when he is afraid, he will not like novelty. He will seek the familiar, staying in his comfort zone, unwilling to leave and explore new things. Children impacted by war, natural disasters, family distress, or violence all have their curiosity crushed.

Disapproval: "Don't touch. Don't climb. Don't yell. Don't take that apart. Don't get dirty. Don't. Don't. Don't." Children sense and respond to our fears, biases, and attitudes. If we convey a sense of disgust at the

mud on their shoes and the slime on their hands, their discovery of tadpoles will be diminished.

Absence: The presence of a caring, invested adult provides two things essential for optimal exploration: 1) a sense of safety from which to set out to discover new things and 2) the capacity to share the discovery and, thereby, get the pleasure and reinforcement from that discovery.

Teacher Tips

- Recognize individual differences in children’s styles of curiosity. Some want to explore with only their minds, others in more physical ways — touching, smelling, tasting, and climbing. To some degree these differences are related to temperamental differences in the exploratory drive. Some children are more timid; others are more comfortable with novelty and physical exploration. Yet even the timid child will be very curious; he may require more encouragement and reinforcement to leave safe and familiar situations.
- Try to redefine "failure." In truth, curiosity often leads to more mess than mastery, but it is how we handle the mess that helps encourage further exploration, and thereby, development. Redefine failure. When the 5-year-old is learning to jump rope and he trips a thousand times, this is not a thousand failures — it is determination.
- Use your attention and approval to reinforce the exploring child. When exploration in the classroom is disruptive or inappropriate, contain it by teaching the child when and where to do that kind of exploration: "Tommy, lets play with water outside."

If we let them, children can reintroduce us to the world. When we truly allow a child to share his discoveries with us, we experience the joys of rediscovery — and in doing so, learn ourselves.

Curiosity	results in	Exploration
Exploration	results in	Discovery
Discovery	results in	Pleasure
Pleasure	results in	Repetition
Repetition	results in	Mastery
Mastery	results in	New Skills
New Skills	results in	Confidence
Confidence	results in	Self esteem
Self esteem	results in	Sense of Security
Security	results in	More Exploration

The Importance of Pleasure in Play

By Bruce Duncan Perry, M.D., Ph.D.

Play takes many forms, but the heart of play is pleasure — an important component in learning.

Some people think of play as the opposite of work. They think of it with goofing off, being lazy, lack of achievement, or, at best, recreation. "Stop playing and get to work!" Yet, as many of you probably know, it is through play that we do much of our learning. We learn best when we are having fun. Play, more than any other activity, fuels healthy development of children — and the continued healthy development of adults.

Play takes many forms, but the heart of all play is pleasure. If it isn't fun, it isn't play. We play from birth on — we play using our bodies (building with blocks) and our minds (fantasy play). We use words to play (jokes, wit, humor) and we use props (blocks, toys, games). While the exact nature of play evolves, becoming more complex as we grow, play at all ages brings pleasure.

What Young Children Know

Play enhances every domain of a child's development. Gross-motor skills, such as walking, kicking, or skipping, can be strengthened when a toddler pushes a toy grocery cart or an older child jumps rope. When a young child kicks a ball across the room, she is practicing coordination by balancing on one foot to kick with the other.

Fine-motor and manipulation skills are developed while a child builds and colors a sign for a backyard tree house. When throwing and catching a ball, a child practices hand-eye coordination and the ability to grasp.

Children practice and develop language skills during play. A child's play with words, including singsong games and rhymes that accompany games of tag, can help him master semantics, practice spontaneous rhyming, and foster word play.

The child's cognitive capacity is enhanced in games by trial and error, problem solving, and practice discriminating between relevant and irrelevant information. Play requires the child to make choices and direct activities and often involves strategy, or planning, to reach a goal.

Interpersonal/social skills, ranging from communication to cooperation, develop in play. Children learn about teamwork when they huddle together and decide who plays each position in a pick-up soccer game. The child gains an understanding about those around him and may become more empathic and less egocentric. When playing with peers, children learn a system of social rules, including ways to control themselves and tolerate their frustrations in a social setting.

The Value of Boredom

Ironically, it is a lack of external stimulation and solitude that facilitates creative play. Often, a child will initially perceive this as "boredom." The child seeks structure and organization from parents or teachers — "I'm bored. I have nothing to do." And all too often we jump in too soon and make the mistake of creating the child's activities for him. We need to learn to let children become bored, because it is through this transient period of under-stimulation that their internal world can come alive. This process is facilitated by solitude — the opportunity to be alone and without too many external stimuli.

When a child cannot watch television, play video games, and is not participating in a scheduled "externally

focused" activity, she will become more internally focused. Her imagination and creativity takes over. She will find and create "toys" from what is available — sticks become dolls, dolls become royalty, and these members of "royalty" become actors in the child's play — rocks become blocks, blocks become walls, and walls create castles.

Playtime Inhibitors

The primary inhibitor of play for American children is television. Watching television is a passive, noncreative time. On average, our children watch 28 hours of television each week — all stealing time from social interactions, abstract thinking, creativity, and play. The use of this passive medium in the classroom should be very limited. An hour of "educational" television does not have the same power as an hour of creative play.

The second major inhibitors of play are adults. Our children are overtired and overscheduled. We wake them before the sun rises and often keep them scheduled in school, after-school programs and lessons, and sports well into the night. They have little time to themselves, and too few opportunities for nonstructured play.

Providing Solitude

One of the most important forms of play is playing with ideas. Abstract thinking is play. When a child fantasizes, he is playing. By taking images, ideas, and concepts from inside their own minds and re-organizing, sorting, and re-connecting in new ways, children create. They create play worlds, hopes, desires, and wishes. They imagine being a ball player, a dancer, a superhero, a teacher. In order to facilitate this, children need more moments of quiet. Children need more solitude. Children need less external, electronic, and structured adult-world stimulation.

Teacher Tips

- Bring more play into the classroom. You do it already, but keep being creative. Word games, number games, role-playing, singing, and dozens of other methods allow you to mix the emotional, social, or cognitive challenge with fun. The more you encourage creativity and tap into the child's sense of fun, the easier it will be to introduce even greater challenges. Sometimes we use recess or free time as currency in a reward system — "Your table will have no recess if all of these blocks are not cleaned up in five minutes." This punishment reflects a fundamental misunderstanding of the value of play in a child's development. We would never withhold a lesson in reading because a child had not managed to finish another assignment.
- Help educate parents about the power of fun. If you sense that parents are pushing their children too much and too early, pass this information along. Tell them about how important solitude and play are to creativity. Help a parent understand that if she provides a safe, nurturing, and enriched environment, her child will do just fine. The playful, creative child who comes to love learning is more likely to achieve and succeed than the anxious, pressured 5-year-old child who knows that "grades are important."
- Don't be afraid of unstructured time. Young children learning social skills need to learn to negotiate, compromise, persuade, and cooperate. When allowed to play, children will do all of these things with each other. When two 5-year-olds argue about how to divide an uneven number of blocks while building a "city," they are learning how to negotiate, compromise, and work together. If the teacher steps in and referees each conflict, they will not practice those skills.

How the Brain Learns Best

Dr. Bruce Perry

Easy ways to gain optimal learning in the classroom by activating different parts of the brain

By [Bruce D. Perry, M.D., Ph.D.](#)

Over the last 40 years we have learned more about the human brain than in the previous 400 years. Educators and neuroscientists have been trying to put this knowledge to work by transforming the information of basic and clinical neurosciences into practical insights for the classroom. In a series of special features, we will be looking at how the brain works and what this can tell us about your teaching.

First, however, it is important to remember that all learning is brain-based. Through the process of education, we are trying literally to change the brain — not the pancreas, spleen, or lungs. Indeed, education is practical neuroscience. That does not mean that every teacher needs to become a neuroscientist or memorize 100 neurotransmitters and 50 brain areas responsible for cognition. But it does mean that teachers can become more effective with some knowledge of how the brain senses, processes, stores, and retrieves information.

Neural System Fatigue

Learning requires attention. And attention is mediated by specific parts of the brain. Yet, neural systems fatigue quickly, actually within minutes. With three to five minutes of sustained activity, neurons become "less responsive"; they need a rest (not unlike your muscles when you lift weights). They can recover within minutes too, but when they are stimulated in a sustained way, they just are not as efficient. Think about the piano and the organ; if you put your finger on the organ key and hold it down it will keep making noise, but the piano key makes one short note, and keeping your finger there produces no more sound. Neurons are like pianos, not organs. They respond to patterned and repetitive, rather than to sustained, continuous stimulation. Why is this important for a teacher?

When a child listens as you say, "George Washington was 6'4" tall," she uses one neural system (call it A). When she is told about a concept related to that fact ("The average height of men during the Revolutionary War was only 5'4", "a slightly different, but functionally interconnected neural set (B) is used. When she listens to a vignette: "Washington, at the darkest moment in the Revolution, when his soldiers were deep in the despair of defeat, starving and freezing at Valley Forge, slowly rose to his full height and, using his dominant personality (in part conveyed by his physical dominance) and was able to motivate his discouraged soldiers to re-enlist and continue fighting," yet other related neural systems are active (C and D). These interrelated neural systems are all important in learning; indeed, our students will learn more completely if they make "changes" (create memory) in all of these neural systems (A, B, C, and D). Facts are empty without being linked to context and concepts.

When a child is in a familiar and safe situation, as in most of our classrooms, his or her brain will seek novelty. So, if this child hears only factual information, she will fatigue within minutes. Only four to eight minutes of pure factual lecture can be tolerated before the brain seeks other stimuli, either internal (e.g., daydreaming) or external (Who is that walking down the hall?). If the teacher is not providing that novelty, the brain will go elsewhere. Continuous presentation of facts or concepts in isolation or in a nonstop series of anecdotes will all have the same fatiguing effect — and the child will not learn as much, nor will she come to anticipate and enjoy learning.

The best presentation, the most engaging and effective teaching, has all three elements. And it is very important how the teacher puts these elements together.

The Bob-and-Weave Lecture

The most effective presentation must move back and forth through these interrelated neural systems, weaving them together. These areas are interconnected under usual circumstances, like a complete "workout" in the gym where we rotate from one station to another. Similarly, in teaching, it is most effective to work one neural area and then move on to another. Engage your students with a story to provide the context. Make sure this vignette can touch the emotional parts of their brains. This will activate and prepare the cognitive parts of the brain for storing information. Information is easiest to digest when there is emotional "seasoning" — humor, empathy, sadness, and fear all make "dry" facts easier to swallow. Give a fact or two; link these facts into related concepts. Move back to the narrative to help them make the connection between this concept and the story. Go back to another fact. Reinforce the concepts. Reconnect with the original story. In and out, bob and weave, among facts, concept, and narrative.

Human beings are storytelling primates. We are curious, and we love to learn. The challenge for each teacher is to find ways to engage the child and take advantage of the novelty-seeking property of the human brain to facilitate learning.

SIDEBAR:

Dr. Bruce D. Perry, M.D., Ph.D., is an internationally recognized authority on brain development and children in crisis. Dr. Perry leads the ChildTrauma Academy, a pioneering center providing service, research and training in the area of child maltreatment (www.ChildTrauma.org). In addition he is the Medical Director for Provincial Programs in Children's Mental Health for Alberta, Canada. Dr. Perry served as consultant on many high-profile incidents involving traumatized children, including the Columbine High School shootings in Littleton, Colorado; the Oklahoma City Bombing; and the Branch Davidian siege. His clinical research and practice focuses on traumatized children-examining the long-term effects of trauma in children, adolescents and adults. Dr. Perry's work has been instrumental in describing how traumatic events in childhood change the biology of the brain. The author of more than 200 journal articles, book chapters, and scientific proceedings and is the recipient of a variety of professional awards.

Twelve Brain Rules

*From
brain rules 12 principles for Surviving and Thriving at
Work, Home, and School
by John Medina*

EXERCISE | Rule #1:

Exercise boosts brain power.

SURVIVAL | Rule #2:

The human brain evolved, too.

WIRING | Rule #3:

Every brain is wired differently.

ATTENTION | Rule #4:

We don't pay attention to boring things.

SHORT-TERM MEMORY | Rule #5:

Repeat to remember.

LONG-TERM MEMORY | Rule #6:

Remember to repeat.

SLEEP | Rule #7:

Sleep well, think well.

STRESS | Rule #8:

Stressed brains don't learn the same way.

SENSORY INTEGRATION | Rule #9:

Stimulate more of the senses.

VISION | Rule #10:

Vision trumps all other senses.

GENDER | Rule #11:

Male and female brains are different.

EXPLORATION | Rule #12:

We are powerful and natural explorers.

Title	Description	Year
<u>Age Appropriate Play: The First Four Years:3 Volume Set</u>	As an educator, you have the crucial role of helping parents and caregivers build healthy families. Age-Appropriate Play: The First Four Years is the perfect tool! This comprehensive three-volume set brings examples of age-appropriate play to life. By teaching parents the importance of these positive interactions, you can help lay the foundation for lifelong learning. With Age-Appropriate Play: The First Four Years, parents will learn to: Promote learning and other developmental skills through play Provide safe, interesting and appropriate learning environments Recognize developmental milestones Volume 1: The First 12 Months Holding, gazing and talking for bonding and stimulation Providing open and safe spaces for learning new gross motor skills Assisting with the emergence of self-awareness using simple games Playing with household objects to develop fine motor skills Ages 13 - Adult 24 minutes. http://www.srpublications.com	2002
<u>Child's Play</u>	Children play their way into adulthood. Learn why play is so important and how it literally "turns kids into adults." Play is the engine that drives child development. Understanding play is key to any unit in child development or parenting education. Explore styles of play, the role of adults, the value of toys. Learn about practice play, parallel and co-operative play, sensory play, creative and symbolic play. www.srpublications.com/child-development/Default.htm	
<u>Importance of Play</u>	Play helps children develop imagination, overcome fears, experiment, and learn to cope with new situations. It also helps children stretch their minds and bodies as well as practice skills needed for future development. (10 min.) A Meridian Production. http://www.srpublications.com	
<u>Play</u>	Play is an essential medium for learning and developing. This module explores the significance of play to all areas of development. In real life sequences, the social categories and the content of children's play are demonstrated. The module closes with a description of the adult in facilitating play. http://www.srpublications.com	
<u>Play and the Social World: Acquiring Social Intelligence</u>	Designed to be a happy place of imagination and cooperation, a playground is too often a danger zone of intimidation and violence. This ageless program explores the educational value and social dynamics of play while emphasizing the importance of a supportive adult presence in the playground environment. Games and techniques used by teachers and psychologists to help children develop interpersonal skills, articulate their feelings, and reflect on their behavior are included, as is information on playground design. (25 minutes, color) http://www.srpublications.com	
<u>Playing</u>	For a child, play is serious fun. This program will help parents, teachers, caregivers, and students	

Title	Description	Year
	understand the complex functions of play. The relationship to objects, whether toys or everyday things, is explored through dozens of scenes of children interacting in classic situations. Discussion by experts and parents and video footage of children at play offer insights into games of imitation, the development of the imagination, stimulation of the senses, and what makes a good toy. Not available in French-speaking Canada. (54 minutes, color) http://www.srpublications.com	
Playtime for you and me [video recording]	Baby Playtime, Inc. ; producer/director, Unique age appropriate interactive play programs for assisting baby's milestone development. Features a mother playfully interacting with babies while focusing on the development of motor skills, strength, balance, movement and coordination. Provides lots of fun activities both in the home and in the playground. For the parents of babies from 0 through 15 months.	2002
The role of play [video recording]	Defines play and discusses some of the functions including gross and fine motor development, cognitive development, creativity, socialization, self-awareness, and therapeutic value. Describes different types of play such as physical play; including sensorimotor, mastery or skill play, and rough-and-tumble play; pretend play; dramatic play; and games with rules. The social character of play and gender differences in play are also discussed.	1992
The value of play [video recording]	Through play, children learn best when experimenting, exploring, and making discoveries and in this program, viewers learn how infants develop play and how play contributes to the total development of a child.	1991
